Exercise E1 Machine-Vision Strobe: Capacitor Charging and Safe Discharge

Result: What is the maximum charging current? How long does it take to charge the capacitor to 90% of the required voltage? What is the capacitor voltage then?
Solution:

Solution:

$$C = \frac{W_e}{U \cdot (1 - 0.9)} = \frac{0.1 \text{ J}}{447.2 \text{ V} \cdot 0.1} = 2.235 \cdot 10^{-4} \text{ F} = 223.5 \text{ nF}$$

At $t=0$, the capacitor is uncharged, therefore the maximum charging current is

$$i_{C, \max} = \frac{U}{R} = \frac{447.2 \text{ V}}{10 \text{ M}\Omega} = 44.72 \text{ }\mu\text{A}$$

The resistor voltage falls exponentially

$$T = RC = 10 \text{ M}\Omega \cdot 223.5 \text{ nF} = 2.235 \text{ ms}$$

Practical engineering approximation is that the capacitor is essentially charged after

$$T_{\text{charge}} = 5 \cdot RC = 11.175 \text{ ms}$$

Energy dissipated as heat in the resistor:

$$W_{\text{diss}} = \frac{U^2}{R} \cdot T_{\text{charge}} = \frac{(447.2 \text{ V})^2}{10 \text{ M}\Omega} \cdot 11.175 \text{ ms} = 2.235 \text{ J}$$

For discharge:

Thus, u_C starts at 447.2 V and approaches 0 V , while u_R starts at 447.2 V and falls to 0 V

with

$$T_2 = R \cdot i_C = 10 \text{ M}\Omega \cdot 44.72 \text{ }\mu\text{A} = 447.2 \text{ ms}$$

Set $u_C(t) = U \cdot e^{-t/T_2}$:

$$10 \text{ ms} = T_2 \cdot \ln\left(\frac{447.2}{316.2}\right) \Rightarrow T_2 = 3.47 \text{ ms}$$

rc circuit, thevenin equivalent, transient response, sensor interface, industrial electronics, chapter1 1

Exercise E2 Industrial Sensor Interface: Source, T-Network and Capacitor

Result: What is the maximum charging current? How long does it take to charge the capacitor to 90% of the required voltage? What is the capacitor voltage then?
Solution:

Solution:

$$U = 12 \text{ V} \quad R_1 = 2 \text{ k}\Omega \quad R_2 = 10 \text{ k}\Omega$$

The capacitor voltage immediately after the switch is closed is

$$u_C(0) = U \cdot \frac{R_2}{R_1 + R_2} = 12 \text{ V} \cdot \frac{10 \text{ k}\Omega}{12 \text{ k}\Omega} = 10 \text{ V}$$

After the capacitor is fully charged, the switch is opened. The load is disconnected. After the capacitor has been charged, a load resistor is connected by a switch.

When the capacitor is fully charged, the switch is closed. The load resistor is connected, the new capacitor voltage is

$$u_C(t) = U_{\text{new}} \cdot e^{-t/T_{\text{new}}}$$

..
$$U_C(t) = U_{0e} + (U_{0e} - U_{0e}) e^{-t/T} = 5 + (5 - 5) e^{-t/5 \times 10^{-3}} = 5 \text{ V}$$

The final value is $U_C = 5 \text{ V}$.

Solution

$$U_C(t) = U_{0e} + (U_{0e} - U_{0e}) e^{-t/T} = 5 + (5 - 5) e^{-t/5 \times 10^{-3}} = 5 \text{ V}$$

Therefore, the capacitor voltage decays exponentially to $U_C = 5 \text{ V}$.

Practical solution: use the equivalent source voltage:

$$U_C(t) = U_{0e} + (U_{0e} - U_{0e}) e^{-t/T} = 5 + (5 - 5) e^{-t/5 \times 10^{-3}} = 5 \text{ V}$$

The time constant is $T = 5 \times 10^{-3} \text{ s} = 5 \text{ ms}$.

$$U_C(t) = 5 + (5 - 5) e^{-t/5 \times 10^{-3}} = 5 \text{ V}$$

$$t_{\text{charge}} \approx 5T = 50 \text{ ms}$$

inductors, air core coil, magnetic field, sensor calibration, transient response, current density, chapter 1

Exercise E3 Hall-Sensor Test Bench: Air-Core Calibration Coil

A. Short and long air core coils are placed in a magnetic field. The magnetic field is homogeneous and the coils are placed in the center of the field. The magnetic field is homogeneous and the coils are placed in the center of the field. The magnetic field is homogeneous and the coils are placed in the center of the field.

Result: The magnetic field is homogeneous and the coils are placed in the center of the field. The magnetic field is homogeneous and the coils are placed in the center of the field.

Solution

Solution

$$I = 22 \text{ mm} \times 20 \text{ mm} \times 0.8 \text{ mm} = 352 \text{ mm}^3$$

Use the following equation to calculate the current density J and the current I :

$$J = \frac{I}{A} = \frac{I}{\pi r^2} = \frac{I}{\pi (0.01)^2} = 10^6 J$$

The coil is connected to a DC source.

Calculate the coil resistance R at room temperature:

$$R = \frac{\rho L}{A} = \frac{1.7 \times 10^{-8} \text{ Ohm}\cdot\text{m} \times L}{\pi (0.01)^2} = 0.54 \text{ Ohm}$$

Solution: The coil resistance is $R = 0.54 \text{ Ohm}$.

Therefore, the total wire length is approximately:

$$L = \frac{R A}{\rho} = \frac{0.54 \text{ Ohm} \times \pi (0.01)^2}{1.7 \times 10^{-8} \text{ Ohm}\cdot\text{m}} = 100 \text{ m}$$

Now the resistance is

```
\begin{align*} R &= \rho_{\text{Cu}} \frac{l_{\text{Cu}}}{A_{\text{Cu}}} \quad \&= 0.0178 \sim \text{mm} \\ \Omega, \text{mm}^2/\text{m} &\cdot \frac{1.571 \sim \text{m}}{0.503 \sim \text{mm}^2} \quad \&= \\ 0.0556 \sim \text{mm} \Omega & \end{align*}
```
